Google Quantum AI- (https://quantumai.google) is a central hub for exploring the possibilities of quantum computing. It provides access to cutting-edge research, hardware, and software tools designed to go beyond classical machine learning. For our purposes, it can serve as a curriculum backbone: we can use its guides and resources to show students how classical concepts (like feature maps in QML Torch) connect to the larger quantum landscape. By integrating these materials, we not only make our sessions more rigorous but also align with practices in the field, helping participants see how their small exercises relate to real world quantum computing advances. Qiskit- (https://qiskit.org/) Qiskit is IBM's open-source framework for quantum computing. It comes with tutorials, simulators, and ready-to-run examples that help students learn both the basics of quantum circuits and their machine learning applications. For beginners, Qiskit's educational material is a great way to see how quantum algorithms are structured, and how they connect to concepts like feature maps and kernels in QML. Scikit-learn- (https://scikit-learn.org/stable/) Scikit-learn is a classical machine learning library in Python, but it is essential for beginners to build the foundation. Many QML Torch examples use datasets and models from scikit-learn (such as logistic regression and the moons dataset). By mastering scikit-learn first, programmers can better understand how feature engineering works and how quantum approaches extend these ideas. (added week of 09/20/2025)

Quantum Computing for the Very Curious- (https://quantum.country/qcvc) This is a free, interactive online textbook that introduces quantum computing concepts from scratch. It uses spaced repetition to help students remember the material over time. It is ideal for absolute beginners who want to develop an intuition for qubits, superposition, and entanglement before diving into programming frameworks. (added week of 09/20/2025)
